### 12.2 Ladder of Powers

Transformina to Achieve Linearity

## What to do if data is non-linear:

## Questions: Watch Video by David Bock "Ladder of Powers"

## Ladder of Powers

Here $V$ represents our variable of interest. We are going to consider this variable raised to a power $\lambda$, i.e. $V^{\lambda}$

We go up the ladder to remove left skewness and down the ladder to remove right skewness.

# Transforming with Powers (don't memorize - see graphs) 

## Facts about powers:

- The graph of a power with exponent 1 is a straight line.
- Powers greater than 1
- give graphs that bend upward.
- The sharpness of the bend increases as the power increases.
- Powers less than 1 but greater than 0
- give graphs that bend downward.
- The logarithm function corresponds to $\mathbf{Y}=0$ (not the same as raising to the 0 power which is just a horizontal line at $y=1$ )
- Powers less than 0
- give graphs that decrease as x increases.
- Greater negative values of result in graphs that decrease more quickly.

## Here are <br> Samples of Graphs <br> and

the
Transformations to create a linear association

Transformation $x$ and $y^{3}$

Transformation $x$ and $y^{\wedge}(1 / 3)$

Transformation $x$ and 1/y ( $y^{-1}$ )

Transformation $x$ and $y^{2}$

Transformation $x$ and $y^{\wedge}(1 / 2)$

Transformation $x$ and $\log (y)$

## The Logarithm Transformation

If an exponential model of the form $\mathrm{y}=a \mathrm{ab}^{\mathrm{x}}$ describes the relationship between x and y then we can use logarithms to transform the data to produce a linear relationship (and vice versa- if a transformation of $(\mathrm{x}, \mathrm{y})$ data to ( $\mathrm{x}, \log \mathrm{y}$ ) straightens our data, we know it's exponential

$$
\begin{aligned}
& \text { Algebraic Properties of Logarithms } \\
& \qquad \log _{b} x=y \quad \text { if and only if } \quad b^{y}=x \\
& \text { The rules for } \log ^{2}=x \text { arithms are } \\
& \text { 1. } \log _{b}(M N)=\log _{b} M+\log _{b} N \\
& \text { 2. } \log _{b}(M / N)=\log _{b} M-\log _{b} N \\
& \text { 3. } \log _{b} X^{p}=p \log _{b} X
\end{aligned}
$$

- So how does this work? well if we have the equation $y=a b^{x}$ and take the $\log$ of both sides:

$$
\begin{aligned}
\log y & =\log \left(a b^{x}\right) \\
& =\log a+\log b^{x} \\
\cdot \quad & =\log a+\log b(x) \quad \text { Does this look familiar?! }
\end{aligned}
$$

## Summary of what you need to know about log transformations

When data doesn't look straight, try both transformations: ( $x, y$ ) to ( $x$, logy) or ( $x$, Iny) and (logx, logy) or (Inx, Iny)- log and natural log are both fine!

Check which transformation did a better job straightening:
Make a scatterplot of each transformation. Do LinReg a+bx to check your $r$ for each. The stronger the $r$, the better.

Also do a residual plot for each transformation to see which better fits the data (for exponential trial: L1, RESID. For Power Law trial: L3, RESID)

If your first transformation was better than it's an underlying exponential function fitting your data. If the second transformation was better than it's a power model.

Find the regression equation for your original untransformed data:

- If it was exponential, yhat $=\left(10^{a}\right)\left(10^{b}\right)^{x}$
- If it was a power model, yhat $=\left(10^{a}\right)\left(x^{b}\right)$
